HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Remarks on the Egyptian 2/D table in favor of a global approach (D prime number)

Abstract

For $h=3$ or 4 , Egyptian decompositions into h unit fractions, like $2/D = 1/D_1 + \dots + 1/D_h$, were given by using $(h-1)$ divisors (d_i) of D_1 . This ancient *modus operandi*, well recognized today, provides $D_i = DD_1/d_i$ for i greater than 1 . Decompositions selected (depending on d_i) have generally been studied by modern researchers through the intrinsic features of d_i itself. An unconventional method is presented here without considering the d_i properties but just the differences $d_{(h-1)} - d_h$. In contrast to widespread ideas about the last denominator like ' D_h smaller than 1000', it is more appropriate to adopt a global boundary of the form ' D_h smaller or equal to $10D$ ', where 10 comes from the Egyptian decimal system. Singular case $2/53$ (with 15 instead of 10) is explained. The number of preliminary alternatives before the final decisions is found to be so low (71) for $h=3$ or 4 that a detailed overview is possible. A simple additive method of trials, independent of any context, can be carried out, namely $2n+1 = d_2 + \dots + d_h$. Clearly the decisions fit with a minimal value of the differences $d_{(h-1)} - d_h$, independently of any d_i values.

Keywords: Rhind Papyrus, 2/n table, Egyptian fractions

Preamble

The recto of the Rhind Mathematical Papyrus (RMP) [1, 2, 3] contains the so-called Egyptian $2/D$ table. The genesis of a project such as build this table will never really be apprehended. This is not a project as impressive as the construction of a pyramid or temple, however it has been well and truly succeeded. It is impossible to doubt that pyramid works have not been carried out without a hierarchy of teams well organized in various specialties. A perfectly organized hierarchy that included team leaders and supervisors.

It is not hard to imagine that a structured similar organization was also used for the $2/D$ table. This table has not been an exercise in style. It is imperative to keep in mind that it can not be the work of a single scribe, but surely results of indefinite periods of trials and improvements done by an elite team of scribes talented for calculating. As it is well known through dialogues of Plato, the idea of a small number of scholars (philosophers) comes frequently. To these people only, was reserved the right to reflect on issues such as calculations or the study of numbers. He knew very well that this type of elite was present in the community of scribes of ancient Egypt. He was also aware of their very advanced knowledges in these areas, but without knowing all secrets. There is no reason today to reject the idea of an elite team or even a chief scribe empowered to decide the last. The time for carrying the table was perhaps over more than a generation ^a, in order to provide a satisfactory completed product. In such a product nothing should have been left to chance and everything has been deliberately chosen. This is not like a school exercise where one can use a decomposition rather than another to solve a given problem.

Once found suitable methods for calculations, it becomes possible to take a look at “the preliminary draft” in its entirety. This look is necessary in order to preserve an overall coherence. Some difficulties thus may be highlighted and resolved by a minimum of general decisions, the simplest as possible. The number of potential solutions appears as considerably lower than *ab initio* unrealistic calculations published in the modern literature [4, 5], namely 22295 or around 28000. We find that it is enough to consider only $71 + 71$ possibilities, then results could be examined before making consistent decisions. This is realistic. A team spirit is very suitable to make obvious the need for a classification and successive resolutions of difficulties encountered during the project progress. Directives given by a leader are implied. All these ideas have put us on the track to a comprehensive approach. These ones are the filigree of our analysis.

I Data from the papyrus

RMP is also well known by the name of his transcriber, the scribe Ahmes. This latter copied the document around 1650 BCE. The source, now lost, could date from XIIth dynasty, a golden age of the middle kingdom. RMP recto shows a table of 2 divided by numbers D from 5 up to 101 into “unit fractions”. Number 3 may be considered as implicitly included, because its decomposition is used in the verso for some problems or it appears elsewhere in Papyrus Kahun [6]. This fact has been commented pertinently by Abdulaziz [7] .

For D prime only (except number 101), we present below a reordered excerpt from the $2/D$ table by using **our favorite red numbers m** , that just show the multiplicity of a denominator with D . Please note that *they are not the red auxiliary numbers used by Ahmes*, ie those “decoded” by Gardner [8], but related with these latter by means of the divisors of the first denominator D_1 .

^aThe creative flash of an inspired scholar (ancient or modern) is short. What is generally much longer is the development of the idea and achievement of tools (theoretical or practical) necessary for its application. Of course once the tools lapse their use takes little time!

Table A: REORDERED $2/D$ TABLE FOR PRIME NUMBERS D

$2/D=1/D_1+1/D_2$ [2-terms]		$2/D=1/D_1+1/D_2+1/D_3$ [3-terms]		$2/D=1/D_1+1/D_2+1/D_3+1/D_4$ [4-terms]	
$2/3 = 1/2 + 1/6$ ₂		$2/13 = 1/8 + 1/52$ ₄ + $1/104$ ₈		$2/29 = 1/24 + 1/58$ ₂ + $1/174$ ₆ + $1/232$ ₈	
$2/5 = 1/3 + 1/15$ ₃		$2/17 = 1/12 + 1/51$ ₃ + $1/68$ ₄		$2/43 = 1/42 + 1/86$ ₂ + $1/129$ ₃ + $1/301$ ₇	
$2/7 = 1/4 + 1/28$ ₄		$2/19 = 1/12 + 1/76$ ₄ + $1/114$ ₆		$2/61 = 1/40 + 1/244$ ₄ + $1/488$ ₈ + $1/610$ ₁₀	
$2/11 = 1/6 + 1/66$ ₆		$2/31 = 1/20 + 1/124$ ₄ + $1/155$ ₅		$2/73 = 1/60 + 1/219$ ₃ + $1/292$ ₄ + $1/365$ ₅	
$2/23 = 1/12 + 1/276$ ₁₂		$2/37 = 1/24 + 1/111$ ₃ + $1/296$ ₈		$2/79 = 1/60 + 1/237$ ₃ + $1/316$ ₄ + $1/790$ ₁₀	
		$2/41 = 1/24 + 1/246$ ₆ + $1/328$ ₈		$2/83 = 1/60 + 1/332$ ₄ + $1/415$ ₅ + $1/498$ ₆	
		$2/47 = 1/30 + 1/141$ ₃ + $1/470$ ₁₀		$2/89 = 1/60 + 1/356$ ₄ + $1/534$ ₆ + $1/890$ ₁₀	
		$2/53 = 1/30 + 1/318$ ₆ + $1/795$ ₁₅			
		$2/59 = 1/36 + 1/236$ ₄ + $1/531$ ₉			
		$2/67 = 1/40 + 1/335$ ₅ + $1/536$ ₈			
		$2/71 = 1/40 + 1/568$ ₈ + $1/710$ ₁₀			
		$2/97 = 1/56 + 1/679$ ₇ + $1/776$ ₈			

II Outlines of a global approach

Actually the whole $2/D$ project can be viewed as a 3-component set (or 3-phases, if you like).

FIRST: discovery of a unique [2-terms] solution, if D is a prime number.

SECOND: for a sub-project [composite numbers] from 9 up to 99, realize that a mini-table, with just four numbers, enables to derive all the composite numbers by using a *multiplicative* operation ^b.

Four numbers, 3, 5, 7, 11 are enough. For instance 99 is reached with 3×33 or 11×9 .

This mini-table, a kind of 'Mother-table', looks as follows:

Table B: Basic Mother-Table

$2/3 = 1/2 + 1/6$ ₂
$2/5 = 1/3 + 1/15$ ₃
$2/7 = 1/4 + 1/28$ ₄
.....
$2/11 = 1/6 + 1/66$ ₆

One sees the first four two-terms decompositions of $2/D$. D being prime, the table is **unique**.

In 'theory', *except if a better decision should be taken*, any fraction $2/D$ (D composite) could be decomposed from this table by dividing a given row by a convenient number. Consider an example: $2/65 = [(\text{row } 2) / (\text{number } 13)] = 1/39 + 1/195$ ₃, what is the solution adopted in the papyrus. As a matter of fact, all decompositions for the sub-project were given in two-terms (except for $2/95$ as a logical consequence of the guidelines adopted by the scribes, that we will justify properly later) ^c.

As the 'Mother-table' has no need to higher value than 11 for the sub-project, we can better understand that, from 13, it could have been decided to leave decompositions into 2 terms.

THIRD: nothing does more obstacle to start a main part of the whole project, namely decompositions into 3 (or 4 terms if necessary), for all prime numbers starting from 13 until 97.

The study carried in this paper is devoted to the third phase.

II.1 General presentation

We could have present the problems in the Egyptian manner, as did Abdulaziz [7] like for example $47 \overline{30} \overline{141} \overline{470}$ what means $2/47 = 1/30 + 1/141 + 1/470$, but we preferred a modern way, more easily understandable to us today. This is unrelated to the spirit in which we thought.

Consider D as given, D_1 is an unknown value to be found. Assume now that d_2, d_3, d_4 are distinct divisors of D_1 , with $d_2 > d_3 > d_4$. These are also unknowns to find.

In order to standardize the notations, D is used for Denominators and d for divisors.

^bIdea already suggested by Gillings [4]

^cAll the Egyptian decompositions for composite numbers are analyzed in our second paper [9]

Look at the following (modern) equations that decompose the 'unity' in 3 or 4 parts:

$$1 = \frac{D}{2D_1} + \frac{d_2}{2D_1} + \frac{d_3}{2D_1}. \quad (\text{II.1})$$

$$1 = \frac{D}{2D_1} + \frac{d_2}{2D_1} + \frac{d_3}{2D_1} + \frac{d_4}{2D_1}. \quad (\text{II.2})$$

It can be viewed under another standpoint like additive operations on integers:

$$2D_1 = D + d_2 + d_3. \quad (\text{II.3})$$

$$2D_1 = D + d_2 + d_3 + d_4. \quad (\text{II.4})$$

Since d_2, d_3, d_4 divide D_1 then we are sure to find Egyptian decompositions. Indeed, dividing by DD_1 we always get sums of unit fractions:

$$\frac{2}{D} = \frac{1}{D_1} + \frac{1}{(D_1/d_2)D} + \frac{1}{(D_1/d_3)D}. \quad (\text{II.5})$$

$$\frac{2}{D} = \frac{1}{D_1} + \frac{1}{(D_1/d_2)D} + \frac{1}{(D_1/d_3)D} + \frac{1}{(D_1/d_4)D}. \quad (\text{II.6})$$

This method was apparently followed [8] in RMP table for prime numbers D from 13 up to 97 . As can be seen, except D_1 , all denominators of each equation appear as a multiple of D , namely

$$D_i = m_i D, \text{ where } m_i = (D_1/d_i). \quad (\text{II.7})$$

Let us briefly summarize the possibilities as follows

$$\frac{2}{D} = \frac{1}{D_1} + \frac{1}{D_2} + \frac{1}{D_3}. \quad (\text{II.8})$$

$$\frac{2}{D} = \frac{1}{D_1} + \frac{1}{D_2} + \frac{1}{D_3} + \frac{1}{D_4}. \quad (\text{II.9})$$

The main task consists in the determination of D_1 and the convenient choice of d_i , from the additive equations (II.3) or (II.4). The d_i 's are the red auxiliary numbers used by the scribe Ahmes.

$$d_i = \frac{D_1}{m_i}. \quad (\text{II.10})$$

III [2-terms] analysis

$$\frac{2}{D} = \frac{1}{D_1} + \frac{1}{D_2}. \quad (\text{III.1})$$

The only comment (admiring) on the subject is that the scribes actually found the right solution (unique) to the problem, namely

$$D_1 = \frac{D+1}{2} \quad \text{and} \quad D_2 = \frac{D(D+1)}{2}. \quad (\text{III.2})$$

IV [3-terms] analysis

Right now consider the [3-terms] cases. Egyptians gave:

Ahmes's selections [3-terms]		Unity decomposition
$2/13 = 1/8 + 1/52_4 + 1/104_8$		$16 = 13 + 2 + 1$
$2/17 = 1/12 + 1/51_3 + 1/68_4$		$24 = 17 + 4 + 3$
$2/19 = 1/12 + 1/76_4 + 1/114_6$		$24 = 19 + 3 + 2$
$2/31 = 1/20 + 1/124_4 + 1/155_5$		$40 = 31 + 5 + 4$
$2/37 = 1/24 + 1/111_3 + 1/296_8$		$48 = 37 + 8 + 3$
$2/41 = 1/24 + 1/246_6 + 1/328_8$	\Leftarrow	$48 = 41 + 4 + 3$
$2/47 = 1/30 + 1/141_3 + 1/470_{10}$		$60 = 47 + 10 + 3$
$2/53 = 1/30 + 1/318_6 + 1/795_{15}$		$60 = 53 + 5 + 2$
$2/59 = 1/36 + 1/236_4 + 1/531_9$		$72 = 59 + 9 + 4$
$2/67 = 1/40 + 1/335_5 + 1/536_8$		$80 = 67 + 8 + 5$
$2/71 = 1/40 + 1/568_8 + 1/710_{10}$		$80 = 71 + 5 + 4$
$2/97 = 1/56 + 1/679_7 + 1/776_8$		$112 = 97 + 8 + 7$

The task of finding D_1 is rather simple, from the moment when one realizes that it is enough to establish a table of odd numbers $(2n+1)_{n \geq 1}$ as a sum of two numbers $d_2 + d_3$, with $d_2 > d_3$. This is easy to do and independent of any context. The table contains n doublets $\{d_2, d_3\}$ and $\sup(d_2) = 2n$. One can start with the lowest values as follows: $d_3 = 1, d_2 = 2, 4, 6, \dots$; $d_3 = 2, d_2 = 3, 5, 7, \dots$ and so on. From Eq.(II.3) the first candidate possible for D_1 starts at an initial value $D_1^0 = (D+1)/2$ as in Fibonacci's studies [10]. We can search for general solutions of the form

$$D_1^n = D_1^0 + n, \quad (\text{IV.1})$$

whence

$$2D_1^n - D = 2n + 1 = d_2 + d_3. \quad (\text{IV.2})$$

Since one of the two D_1 divisors $\{d_2, d_3\}$ is even, then D_1 can not be odd, it must be even. This was rightly stressed by Bruins [11]. From the first table of doublets, a new table (of trials) is built, where this time doublets are selected if d_2, d_3 divide $[(D + d_2 + d_3)/2]$. This provides a D_1^n possible. In this favorable case, first D_3 is calculated by DD_1/d_3 , then D_2 by DD_1/d_2 . For D given, the table of trials defined by the equation just below

$$2n + 1 = d_2 + d_3, \quad \text{where } d_2 \text{ and } d_3 \text{ divide } D_1^n, \quad (\text{IV.3})$$

is bounded by a n_{max}^d . By simplicity in our tables, D_1^n will not be written as $D_1^n(d_2, d_3)$. Even by hand, a realization of this table takes few time. For example decompositions into 3 terms lead to a total of trials with only 71 possibilities! From this low value, it is conceivable to present all results according to an appropriate parameter. Once found a d_3 , a good idea would be select a d_2 the closest as possible of d_3 . This provides a type of classification never glimpsed to our knowledge. Thus, a key parameter of our paper is defined as follows:

$$\Delta_d = d_2 - d_3. \quad (\text{IV.4})$$

Remarks: Clearly Eq. (IV.3) is related to Bruins's method of "parts" redistribution d_2, d_3 [11]. However our method is 'artisanal' and does not need to know the arithmetic properties of D_1 . Once D given, D_1^n are found by trials, without calculations. Unlike to Bruins which sought some forms of D_1 for finding then possible D values. The approach is quite different as well as the reasons justifying the Egyptian choices.

Although our conceptual formalism is different from that of Abdulaziz [7], we (fortunately) found some similarities, but also elements without counterpart to us. A welcome unison is the following: Let us consider its fractional parameter $[R]$ that is crucial for all its analyses. In our notations we find

$$D_1[R] = (2D_1 - D) = 2n + 1 = d_2 + d_3, \quad (\text{IV.5})$$

or equivalently expressed

$$[R] = \frac{1}{(D_1/d_2)} + \frac{1}{(D_1/d_3)}. \quad (\text{IV.6})$$

When it is said "... keeping the terms of $[R]$ less than 10 was an essential part of determining how $2:n$ is to be decomposed.", this should be understood as $(D_1/d_3) \leq 10$ and formulated for us as the condition (IV.8) with a Top-flag $T_f^{[3]} = 10$. (See below for our Top-flag definition)

^dIt can be proved that no solution can be found beyond $n = (D-3)/2$.

However note that the ‘necessity’ of our Top-flag comes directly from the value of D , without constituting a check on D_1 . That only follows from Eq. (IV.7).

In contrast, parameter $[Q]$, defined in Ref. [7] by $[Q] = 1 - [R]$, does not appear to us and plays no role in our analyses. In addition, as the impact of closeness (Δ_d) does not seem to have been apprehended, it is clear that our argumentation will generally be different. Even if, for some ‘easy’ cases, we agree.

In short, for producing their final table, we assume that the scribes have analyzed all preliminary trial results before doing their choice among various alternatives, considered in their totality, not individually.

Furthermore, due to decimal numeration used by ancient Egyptians, one can easily understand that a boundary with a Top-flag $\top_f^{[3]}$ for the last denominator was chosen with a priority value equal to **10** (if possible according to the results given by trials).

The idea of a Top-flag is far to be a ‘*deus ex machina*’. It naturally arises if we try to solve the problem of decomposition in full generality. See Appendix A for more details.

Chief scribe wisely decided to impose an upper bound to all the denominators D_3 , such that

$$D_3 \leq D \top_f^{[3]}. \quad (\text{IV.7})$$

This cut-off beyond $\top_f^{[3]}$ is equivalent to a mathematical condition on D_1 :

$$D_1 \leq d_3 \top_f^{[3]}. \quad (\text{IV.8})$$

Remark that this condition might be exploited from the beginning of the calculations for avoiding to handle too large denominators D_3 . Simply find d_3 , find d_2 , then calculate D_1 , if condition (IV.8) is not fulfilled then quit, do not calculate D_3 , D_2 and go to next values for d_3 , d_2 , D_1 and so on.

Actually, if we follow the method of trials for finding the good choices in the order $d_3 \rightarrow d_2 \rightarrow D_1$, we are naturally led to be careful of the closeness of d_2 , d_3 , measured by Δ_d . This can suggest the idea of a classification according to increasing values of Δ_d .

Since this classification seriously enlightens many solutions chosen by the scribes, it is not impossible to imagine that this ‘*artisan method*’ was actually followed. This is a plausible hypothesis, valueless of evidence obviously. An advantage is also that a similar classification can be applied to the decompositions into 4 terms with the same success, see Sect. V.

The symbol Eg will be used for indicating Egyptian selections in our tables.

Let us now display a preliminary table of trials, see Table C.

Table C: Table of trials [3-terms] with increasing order of Δ_d , only 71 possibilities !

Table of trials [3-terms] with increasing order of Δ_d						
n	$2n+1$	d_2	d_3	Δ_d	D_1^*	Possible [3-terms] decompositions
1	3	2	1	1	8	$2/13 = 1/8 + 1/52_4 + 1/104_8^{Eg}$
1	3	2	1	1	10	$2/17_a = 1/10 + 1/85_5 + 1/170_{10}$
3	7	4	3	1	12	$2/17_b = 1/12 + 1/51_3 + 1/68_4^{Eg}$
2	5	3	2	1	12	$2/19 = 1/12 + 1/76_4 + 1/114_6^{Eg}$
1	3	2	1	1	16	$2/29 = 1/16 + 1/232_8 + 1/464_{16}$
2	5	3	2	1	18	$2/31_a = 1/18 + 1/186_6 + 1/279_9$
4	9	5	4	1	20	$2/31_b = 1/20 + 1/124_4 + 1/155_5^{Eg}$
1	3	2	1	1	20	$2/37 = 1/20 + 1/370_{10} + 1/740_{20}$
1	3	2	1	1	22	$2/41_a = 1/22 + 1/451_{11} + 1/902_{22}$
3	7	4	3	1	24	$2/41_b = 1/24 + 1/246_6 + 1/328_8^{Eg}$
2	5	3	2	1	24	$2/43 = 1/24 + 1/344_8 + 1/516_{12}$
1	3	2	1	1	28	$2/53 = 1/28 + 1/742_{14} + 1/1484_{28}$
1	3	2	1	1	32	$2/61 = 1/32 + 1/976_{16} + 1/1952_{32}$
2	5	3	2	1	36	$2/67 = 1/36 + 1/804_{12} + 1/1206_{18}$
4	9	5	4	1	40	$2/71_a = 1/40 + 1/568_8 + 1/710_{10}^{Eg}$
6	13	7	6	1	42	$2/71_b = 1/42 + 1/426_6 + 1/497_7$
1	3	2	1	1	38	$2/73 = 1/38 + 1/1387_{19} + 1/2274_{38}$
2	5	3	2	1	42	$2/79 = 1/42 + 1/1106_{14} + 1/1659_{21}$
1	3	2	1	1	46	$2/89_a = 1/46 + 1/2047_{23} + 1/4094_{46}$
3	7	4	3	1	48	$2/89_b = 1/48 + 1/1068_{12} + 1/1424_{16}$
1	3	2	1	1	50	$2/97_a = 1/50 + 1/2425_{25} + 1/4850_{50}$
7	15	8	7	1	56	$2/97_b = 1/56 + 1/679_7 + 1/776_8^{Eg}$
3	7	5	2	3	10	$2/13 = 1/10 + 1/26_2 + 1/65_5$
2	5	4	1	3	12	$2/19 = 1/12 + 1/57_3 + 1/228_{12}$
2	5	4	1	3	24	$2/43 = 1/24 + 1/258_6 + 1/1032_{24}$
3	7	5	2	3	30	$2/53 = 1/30 + 1/318_6 + 1/795_{15}^{Eg}$
2	5	4	1	3	32	$2/59 = 1/32 + 1/472_8 + 1/1888_{32}$
2	5	4	1	3	36	$2/67_a = 1/36 + 1/603_9 + 1/2412_{36}$
6	13	8	5	3	40	$2/67_b = 1/40 + 1/335_5 + 1/536_8^{Eg}$
3	7	5	2	3	40	$2/73 = 1/40 + 1/1584_8 + 1/1460_{20}$
2	5	4	1	3	44	$2/83 = 1/44 + 1/913_{11} + 1/3652_{44}$
3	7	6	1	5	12	$2/17 = 1/12 + 1/34_2 + 1/204_{12}$
4	9	7	2	5	14	$2/19 = 1/14 + 1/38_2 + 1/133_7$
3	7	6	1	5	18	$2/29 = 1/18 + 1/87_3 + 1/522_{18}$

As it is clear from Table C an obvious preference for the smallest Δ_d seems to be well followed. After cut-off by $\tau_f^{[3]} = 10$ Table C is reduced and allows us to analyze the following options:

Table D: 3-terms options

Trials [3-terms] ordered with $\Delta_d \nearrow^*$ showing where are the Egyptian options						
n	$2n+1$	d_2	d_3	Δ_d	D_1^n	[3-terms] decompositions $m_3 \leq 10$

6	13	10	3	7	30	$2/47 = 1/30 + 1/141_3 + 1/470_{10}$ Eg

This table shows rare instances where multipliers m_2, m_3 are consecutive. It is always an interesting quality that does not require sophisticated mathematical justification. That will be denoted by a asterisk *. Two instances are found also in [4-terms] series with m_2, m_3, m_4 , see Section V. Just as an indication, we display below the cases dropped out of a [3-terms] decomposition:

Table E: Fractions to be broken down into 4-terms

Table of trials [3-terms] for fractions to be broken down into 4-terms						
n	$2n+1$	d_2	d_3	Δ_d	D_1^n	Possible [3-terms] decompositions

15	31	30	1	29	60	$2/89 = 1/60 + 1/178_2 + 1/5340_{60}$

Our definition of τ_f does not depend on a arbitrary value of D_3 fixed to 1000 as often assumed in the literature. It depends only on the circumstances imposed by the current project. Subdivide now table D into 3 sets according to the properties of each D . A first with a only one Δ_d , a second with two different Δ_d and a third with two conflicting identical Δ_d . That yields:

Table F: A single Δ_d [3-terms]

D with a single Δ_d (options: no)						Scribes's decision: obvious
n	$2n+1$	d_2	d_3	Δ_d	D_1^n	[3-terms] decomposition
3	7	4	3	1	24	$2/41 = 1/24 + 1/246_6 + 1/328_8$ ^{Eg}
7	15	8	7	1	56	$2/97 = 1/56 + 1/679_7 + 1/776_8$ ^{Eg*}
6	13	8	5	3	40	$2/67 = 1/40 + 1/335_5 + 1/536_8$ ^{Eg}
5	11	8	3	5	24	$2/37 = 1/24 + 1/111_3 + 1/296_8$ ^{Eg}
6	13	9	4	5	36	$2/59 = 1/36 + 1/236_4 + 1/531_9$ ^{Eg}
6	13	10	3	7	30	$2/47 = 1/30 + 1/141_3 + 1/470_{10}$ ^{Eg}

Table G: Two different Δ_d [3-terms]

D with two different Δ_d (options: yes)						Scribes's decision: smallest Δ_d
n	$2n+1$	d_2	d_3	Δ_d	D_1^n	[3-terms] decompositions
1	3	2	1	1	8	$2/13 = 1/8 + 1/52_4 + 1/104_8$ ^{Eg}
3	7	5	2	3	10	$2/13 = 1/10 + 1/26_2 + 1/65_5$
2	5	3	2	1	12	$2/19 = 1/12 + 1/76_4 + 1/114_6$ ^{Eg}
4	9	7	2	5	14	$2/19 = 1/14 + 1/38_2 + 1/133_7$

Table H: Two conflicting identical Δ_d [3-terms]

D with two conflicting identical Δ_d (options: yes)						Scribes's decision: consecutive multipliers
n	$2n+1$	d_2	d_3	Δ_d	D_1^n	[3-terms] decompositions
1	3	2	1	1	10	$2/17_a = 1/10 + 1/85_5 + 1/170_{10}$
3	7	4	3	1	12	$2/17_b = 1/12 + 1/51_3 + 1/68_4$ ^{Eg*}
2	5	3	2	1	18	$2/31_a = 1/18 + 1/186_6 + 1/279_9$
4	9	5	4	1	20	$2/31_b = 1/20 + 1/124_4 + 1/155_5$ ^{Eg*}
						Scribes's decision: $2n \leq 10$
n	$2n+1$	d_2	d_3	Δ_d	D_1^n	[3-terms] decompositions
4	9	5	4	1	40	$2/71_a = 1/40 + 1/568_8 + 1/710_{10}$ ^{Eg}
6	13	7	6	1	42	$2/71_b = 1/42 + 1/426_6 + 1/497_7$ *

Remark: *in the cases involving options possible, and in these cases only*, the solutions for $\{2/D = 2/13, 2/19, 2/17, 2/31\}$ were chosen respectively in the set $\{n = 1, 2, 3, 4\}_{2n \leq 10}$. For ruling on $2/71$ there is no convincing arithmetical argumentation, then the choice could have been the simplicity and direct observation: once again a boundary like $2n \leq 10$ is used for picking $n = 4$. That's it. Too simple, but why not?

After this natural selection by cut-off with a Top-flag $\top_f^{[3]} = 10$ and appropriate decisions, it remains some cases to be examined, especially these with $10 < m_3 \leq 16$ because of the singular status of $2/23$, that the scribes will retain with a decomposition into 2 terms. We display below these cases. Of course $2/61$, $2/83$ are *ex officio* excluded from the analysis.

(Anticipation is made on [4-terms] analysis and related decisions that follow, like $\top_f^{[4]} = 10$)

Table I: Dynamic comparison for transitions $3 \Rightarrow 4$

Unique [2-terms] solution									
$2/23 = 1/12 + 1/276$ 12 ^{Eg}									
Selected trials [3-terms] for $2/23$ <i>enigma?</i> ($\mathbf{m}_3 = 16$)

23	47	20	15	12	3	60	$2/73_c = 1/60 + 1/219$ 3 $+ 1/292$ 4 $+ 1/365$ 5 ^{Eg*}		

We repeat that we are always in a logic of a construction site with difficulties arising in different parts of the project. Problems are processed case after case and do not interfere with another previous part. If not, all becomes incomprehensible. A overview supervised by a chief scribe can not be conflicted. The 6 cases presented above confront us with a *dynamic alternative*: *select the transition from 3 to 4 fractions, or reject it*. This exceptional situation is new in the table construction project, as well as the solution itself! It can be observed that 5 cases on 6 have in common the fact that a same denominator appears in [3-terms] and [4-terms] decompositions. *A priori*, this fact may be seen as not being an improvement to better decompose a [3-terms] fraction into [4-terms]. Unless we find a real improvement worthwhile.

$\boxed{2/89}$: sixth case, out of the category ‘same denominator’, is quickly ruled and [4-terms] decomposition is adopted. (Anyway it belonged to this table only because $m_3 = 16$).

$\boxed{2/43}$: once dropped out the option $m_3 = 15$, due to a too high gap $\Delta_d = 13$, the same argument holds, then [4-terms] decomposition is adopted.

$\boxed{2/73}$: the [4-terms] expansion provides an improvement since that leads to three consecutive multipliers $\{3, 4, 5\}$, thus this solution is adopted.

Three cases (slightly reordered) remain to be solved, they are displayed in the following table.

Unique [2-terms] solution									
$2/23 = 1/12 + 1/276$ Eg									
Selected trials [3-terms] for $2/23$ <i>enigma?</i> ($m_3 = 16$)									
n	$2n+1$	d_2	d_3	Δ_d	D_1^n	Unique [3-terms] decomposition			
4	9	8	1	7	16	$2/23 = 1/16 + 1/46$ 2 + $1/368$ 16			
Selected trials [4-terms] $2/23$

15	31	15	10	6	4	30	$2/29_c = 1/30 + 1/58$ 2 + $1/87$ 3 + $1/145$ 5		

For each fraction the same denominators (inside a box) have a well defined position in a [3-terms] expansion and another in a [4-terms]. We denote respectively these positions by $\text{rank}^{[3]}$ and $\text{rank}^{[4]}$. Same denominators will be denoted by $\boxed{\text{same}D_i}$. The table below summarizes the situation.

Fraction	$\boxed{\text{same}D_i}$	$\text{rank}^{[3]}$	$\text{rank}^{[4]}$	Appreciation on ranks
$2/23$	$\boxed{46}$	2	2	no interest
$2/53$	$\boxed{318}$	2	3	too near
$2/29_a$	$\boxed{232}$	2	4	acceptable + smallest Δ_d'

Some convenient rulings ensue, namely

$2/23$; no solution; then come back to the only one solution in 2 terms.

$2/53$; maintain [3-terms] solution; reject [4-terms] solution.

$2/29_a$; adopt [4-terms] solution.

V [4-terms] analysis

Right now consider the [4-terms] cases. Egyptians gave:

Ahmes's selections [4-terms]	Unity decomposition
$2/29 = 1/24 + 1/58_2 + 1/174_6 + 1/232_8$	$48 = 29 + 12 + 4 + 3$
$2/43 = 1/42 + 1/86_2 + 1/129_3 + 1/301_7$	$84 = 43 + 21 + 14 + 6$
$2/61 = 1/40 + 1/244_4 + 1/488_8 + 1/610_{10}$	$80 = 61 + 10 + 5 + 4$
$2/73 = 1/60 + 1/219_3 + 1/292_4 + 1/365_5$	$120 = 73 + 20 + 15 + 12$
$2/79 = 1/60 + 1/237_3 + 1/316_4 + 1/790_{10}$	$120 = 79 + 20 + 15 + 6$
$2/83 = 1/60 + 1/332_4 + 1/415_5 + 1/498_6$	$120 = 83 + 15 + 12 + 10$
$2/89 = 1/60 + 1/356_4 + 1/534_6 + 1/890_{10}$	$120 = 89 + 15 + 10 + 6$

The task of finding D_1 is rather simple, from the moment when one realizes that it is enough to establish a table of odd numbers $(2n+1)_{|n \geq 3}$ as a sum of three numbers $d_2 + d_3 + d_4$, with $d_2 > d_3 > d_4$. This is easy to do and independent of any context. The table contains $([\frac{n}{2}][\frac{n+1}{2}]-1)$ triplets $\{d_2, d_3, d_4\}$ and $\sup(d_2) = 2n-2$. Square brackets here $[]$ means 'integral part of'. One can start with the lowest values as follows: $d_4 = 1, d_3 = 2, 3, 4, \dots, d_2 = 3, 4, 5, \dots; d_4 = 2, d_3 = 3, 4, 5, \dots, d_2 = 4, 5, 6, \dots$ and so on, with the condition $d_3 + d_2 \equiv d_4 + 1 \pmod{2}$.

From Eq.(II.4) the first candidate possible for D_1 starts at the value $D_1^0 = (D+1)/2$. We can search for general solutions of the form

$$D_1^n = D_1^0 + n, \quad (\text{V.1})$$

whence

$$2D_1^n - D = 2n + 1 = d_2 + d_3 + d_4. \quad (\text{V.2})$$

From the first table of triplets, a new table (of trials) is built, where this time triplets are selected if d_2, d_3, d_4 divide $[(D + d_2 + d_3 + d_4)/2]$. This provides a D_1^n possible. In this favorable case, first D_4 is calculated by DD_1/d_4 , then D_3 by DD_1/d_3 , and D_2 by DD_1/d_2 .

This table of trials, properly defined by the equation just below (included the constraints), ie

$$2n + 1 = d_2 + d_3 + d_4, \quad \text{where } d_2, d_3 \text{ and } d_4 \text{ divide } D_1^n, \quad (\text{V.3})$$

is obviously a bit longer to establish than for doublets. By simplicity D_1^n will be not written as $D_1^n(d_2, d_3, d_4)$. For decompositions into 4 terms the total of trials yields only 71 possibilities !

Of course our remark previously made about doublets is still valid for triplets. Likewise, Abdulaziz's parameter $[R]$ takes the form

$$[R] = \frac{1}{(D_1/d_2)} + \frac{1}{(D_1/d_3)} + \frac{1}{(D_1/d_4)}. \quad (\text{V.4})$$

The notation used in our tables will be

$$\Delta'_d = d_3 - d_4, \quad (\text{V.5})$$

Chief scribe wisely decided to impose a upper bound to all the denominators D_4 , such that

$$D_4 \leq D \top_f^{[4]}. \quad (\text{V.6})$$

This cut-off beyond $\top_f^{[4]}$ is equivalent to a mathematical condition on D_1 :

$$D_1 \leq d_4 \top_f^{[4]}. \quad (\text{V.7})$$

Here again, choosing $\top_f^{[4]} = 10$ is quite appropriate. Thus a general coherence is ensured

throughout the project, since 11 out of 12 decompositions into 3 terms were solved with $\top_f^{[3]} = 10$.

Remark that the condition (V.7) might be exploited from the beginning of the calculations for avoiding to handle too large denominators D_4 . Simply find d_4 , find d_3 , find d_2 , calculate D_1 , if (V.7) is not fulfilled then quit, do not calculate D_4, D_3, D_2 and go to next values for d_4, d_3, d_2, D_1 etc.

Table J: Table of trials [4-terms] with increasing order of Δ'_d , only 71 possibilities !

Trials [4-terms] with increasing order of Δ'_d									
n	$2n+1$	d_2	d_3	d_4	Δ'_d	D_1^n	Possible [4-terms] decompositions

33	67	39	26	2	24	78	$2/89 = 1/78 + 1/178_2 + 1/267_3 + 1/3471_{39}$		

Table J shown above is only as an indication for us and, certainly, was not calculated in its entirety. 2/23 has been reported only for memory because it was solved at the end of Sect. IV. With their experience related to 3-terms series, cut-off beyond 10 has been applied by the scribes. Indeed all cases (here 7) may support this cut-off without any exception. Table J becomes:

Table K: [4-terms] options

Trials [4-terms] ordered with $\Delta'_d \nearrow$ showing where are the Egyptian options							
n	$2n+1$	d_2	d_3	d_4	Δ'_d	D_1^n	Possible [4-terms] decompositions $\mathbf{m}_4 \leq 10$
9	19	12	4	3	1	24	$2/29 = 1/24 + 1/58_2 + 1/174_6 + 1/232_8$ Eg
9	19	10	5	4	1	40	$2/61 = 1/40 + 1/244_4 + 1/488_8 + 1/610_{10}$ Eg
14	29	14	8	7	1	56	$2/83 = 1/56 + 1/332_4 + 1/581_7 + 1/664_8$
5	11	5	4	2	2	20	$2/29 = 1/20 + 1/116_4 + 1/145_5 + 1/290_{10}$
18	37	15	12	10	2	60	$2/83 = 1/60 + 1/332_4 + 1/415_5 + 1/498_6$ Eg^*
18	37	21	9	7	2	63	$2/89 = 1/63 + 1/267_3 + 1/623_7 + 1/801_9$
8	17	10	5	2	3	20	$2/23 = 1/20 + 1/46_2 + 1/92_4 + 1/230_{10}$
23	47	20	15	12	3	60	$2/73 = 1/60 + 1/219_3 + 1/292_4 + 1/365_5$ Eg^*
15	31	15	10	6	4	30	$2/29 = 1/30 + 1/58_2 + 1/87_3 + 1/145_5$
14	29	15	9	5	4	45	$2/61 = 1/45 + 1/183_3 + 1/305_5 + 1/549_9$
15	31	15	10	6	4	60	$2/89 = 1/60 + 1/356_4 + 1/534_6 + 1/890_{10}$ Eg
20	41	21	14	6	8	42	$2/43 = 1/42 + 1/86_2 + 1/129_3 + 1/301_7$ Eg
20	41	20	15	6	9	60	$2/79 = 1/60 + 1/237_3 + 1/316_4 + 1/790_{10}$ Eg

We follow the same way as for the [3-terms] series with slightly different subsets. That yields:

Table L: A single or two different Δ'_d [4-terms]

D with a single Δ'_d (options: no)							Scribes's decision: obvious
n	$2n+1$	d_2	d_3	d_4	Δ'_d	D_1^n	[4-terms] decompositions
23	47	20	15	12	3	60	$2/73 = 1/60 + 1/219_3 + 1/292_4 + 1/365_5$ Eg^*
20	41	21	14	6	8	42	$2/43 = 1/42 + 1/86_2 + 1/129_3 + 1/301_7$ Eg
20	41	20	15	6	9	60	$2/79 = 1/60 + 1/237_3 + 1/316_4 + 1/790_{10}$ Eg
D with two different Δ'_d (options: yes)							Scribes's decision: smallest Δ'_d
n	$2n+1$	d_2	d_3	d_4	Δ'_d	D_1^n	[4-terms] decompositions
9	19	12	4	3	1	24	$2/29 = 1/24 + 1/58_2 + 1/174_6 + 1/232_8$ Eg
5	11	5	4	2	2	20	$2/29 = 1/20 + 1/116_4 + 1/145_5 + 1/290_{10}$
15	31	15	10	6	4	30	$2/29 = 1/30 + 1/58_2 + 1/87_3 + 1/145_5$
9	19	10	5	4	1	40	$2/61 = 1/40 + 1/244_4 + 1/488_8 + 1/610_{10}$ Eg
14	29	15	9	5	4	45	$2/61 = 1/45 + 1/183_3 + 1/305_5 + 1/549_9$
							Scribes's decision: consecutive multipliers
n	$2n+1$	d_2	d_3	d_4	Δ'_d	D_1^n	[4-terms] decompositions
14	29	14	8	7	1	56	$2/83 = 1/56 + 1/332_4 + 1/581_7 + 1/664_8$
18	37	15	12	10	2	60	$2/83 = 1/60 + 1/332_4 + 1/415_5 + 1/498_6$ Eg^*
							Scribes's decision: no odd denominator D_1
n	$2n+1$	d_2	d_3	d_4	Δ'_d	D_1^n	[4-terms] decompositions
18	37	21	9	7	2	63	$2/89 = 1/63 + 1/267_3 + 1/623_7 + 1/801_9$
15	31	15	10	6	4	60	$2/89 = 1/60 + 1/356_4 + 1/534_6 + 1/890_{10}$ Eg

We recall that any odd denominator D_1 could lead to a solution for [3-terms] decompositions as checked in tables D or E. Its occurrence arises only 2 times in table L [4-terms]. The first, for 2/61, was dropped out because a $\Delta'_d = 4$ too high. The second one regards 2/89 (first row). Then, for a unifying sake and avoiding singularity, chief scribe decided to discard $D_1 = 63$ in this case.

Remark that we are very far from assumptions of Gillings [4] about Egyptian preferences for even numbers instead of odd, regarding the denominators in general. Thus the 'no odd precept' was

a low priority. At low ratio also (2 times only), this will be applied to the composite numbers D [9].

VI Conclusion

As we saw, the most recent analysis (2008) has been performed on the ‘ $2/n$ ’ table by Abdulaziz [7] (see his group G_2). It can be appreciated as a kind of mathematical anastylis using materials issued from the RMP and other documentation. Ancient calculation procedure, using mainly fractions, is faithfully respected, but leads to arithmetical depth analyses of each divisor of D_1 .

Our global approach avoided the difficulties of sophisticated arithmetical studies. This provides the advantage of forgetting quickly some widespread ‘modern’ ideas about the topic.

- No, the last denominator is not bounded by a fixed value of 1000. It only depends on the ‘circumstances’ related to the value of D . For 3 or 4 terms, a limitation like $D_h \leq 10D$ is quite suitable, except only for $2/53$ where 10 is replaced by 15. An observation well stressed in Ref. [7].
- No requirement is found about the denominator D_1 as having to be the greatest if alternatives.
- Once for all, a systematic predilection for even denominators does not need to be considered. Only once, we were forced to discard $D_1 = 63$ (odd) for deciding on $2/89$.
- Of course, there is no theoretical formula that can give immediately the first denominator as a function of D . It must necessarily go through trials and few selection criteria. The simpler the better, like the Δ -classification presented in this paper. Maybe is it this classification that induces the opportunity of a comprehensive approach ? Strictly speaking, there are no algorithms in the method, just tables and pertinent observation. This is how $2/23$, $2/29$ or $2/53$ have found a logical explanation, more thorough than the arguments commonly supplied for these ‘singularities’.

Find a simple logic according to which there is no singular case was the goal of the present paper. Perhaps, chronologically, the study of prime numbers has been elaborated **before** that of composite numbers. It is nothing more than an hypothesis consistent with the spirit of our study. Yes ancient scribes certainly have been able to calculate and analyze all the preliminary cases. Ultimately, our unconventional method allows to reconstruct the table fairly easily with weak mathematical assumptions, except maybe the new idea to consider as beneficial to have consecutive multipliers.

Appendix A: why a boundary with a Top-flag?

In this appendix, we continue to consider prime denominators D . For [2-terms] decompositions this concept of a Top-flag has no meaning since the last denominator is unique. Obviously, doubtless far from Egyptian concepts, there are another equations **more general** than Eqs. (II.5) or (II.6), namely

$$\frac{2}{D} = \frac{1}{D_1} + \frac{1}{m_2 D} + \frac{1}{m_3 D}. \quad (\text{A.1})$$

$$\frac{2}{D} = \frac{1}{D_1} + \frac{1}{m_2 D} + \frac{1}{m_3 D} + \frac{1}{m_4 D}. \quad (\text{A.2})$$

We can imagine these as issued from another kind of unity decomposition like

$$1 = \frac{D}{2D_1} + \frac{1}{2m_2} + \frac{1}{2m_3}. \quad (\text{A.3})$$

$$1 = \frac{D}{2D_1} + \frac{1}{2m_2} + \frac{1}{2m_3} + \frac{1}{2m_4}. \quad (\text{A.4})$$

$D/2D_1$ remains in the lead of equality and 1 is a sum of terms, each with a even denominator .

These (modern) equations have additional solutions of no use for the scribes .

A priori the solutions are infinite, then for avoiding such a tedious research (today and in the past time), it is necessary to limit the highest denominator $D_h = m_h D$. How to do that ? Simply by defining a kind of ‘Top-flag’ $\top_f^{[h]}$ such as

$$D_h \leq D \top_f^{[h]}. \quad (\text{A.5})$$

Indeed, as soon as one decides to study a three-terms decomposition or more, it should be realized that an upper boundary for the last denominator has to be fixed. If not, the number of solutions

becomes infinite [countable]. Recall that $m_2 < m_3 < m_4$ and $D_2 < D_3 < D_4$. Unfortunately (or not) the author of this paper has begun the calculations with a even more general problem, this of solving

$$\frac{2}{D} = \sum_{i=1}^h \frac{1}{D_i}, \quad (\text{A.6})$$

without any criteria of multiplicity involving multipliers like m_i ($i > 2$).

Certainly this was the reflex of Gillings [4] or Bruckheimer and Salomon [5]. The problem is solvable and the solutions available by means of a small computer. After a necessary arithmetical analysis, it can be found that $(h - 1)$ sets of solutions exist. One with $(h - 1)$ multipliers m_i , another with $(h - 2)$ multipliers and so on. No solution exists if one searches for D_i ($i \geq 2$) not multiple of D . Even a low-level programming code like **sb** can be used instead of **Fortran** to perform computations in a very acceptable speed. We quickly realized the necessity of stopping the calculations by using a limitation regarding the last highest denominator D_h . Whence the introduction of a Top-flag. Actually the Egyptian $2/D$ table shows a subset of more general solutions because the multipliers m_i have a specific form involving D_1 and some of its divisors d_i . For example out of this subset, you can find an unexpected [4-terms] solution for $2/23$ with $\top_f^{[4]} = 10$, namely

$$\boxed{2/23 = 1/15 + 1/115_5 + 1/138_6 + 1/230_{10}}.$$

So, if we restrict ourself to retrieve Egyptian fractions given in the table, it naturally comes to mind to limit the highest denominator by an upper boundary: a convenient Top-flag.

Excepted the Babylonian system example in base 60, a numeration in base 10 is rather universal, because of our two hands with each 5 fingers. It is of common sense that the selection was generally $\top_f^{[h]} = 10$ ($= 2 \times 5$), not excluding a favorable appreciation for $\top_f^{[3]} = 15$ ($= 3 \times 5$) as for $2/53$.
